

Spatiotemporal no-stationarity in environmental avian community assembly rules

1. Temporal variation in variable importance

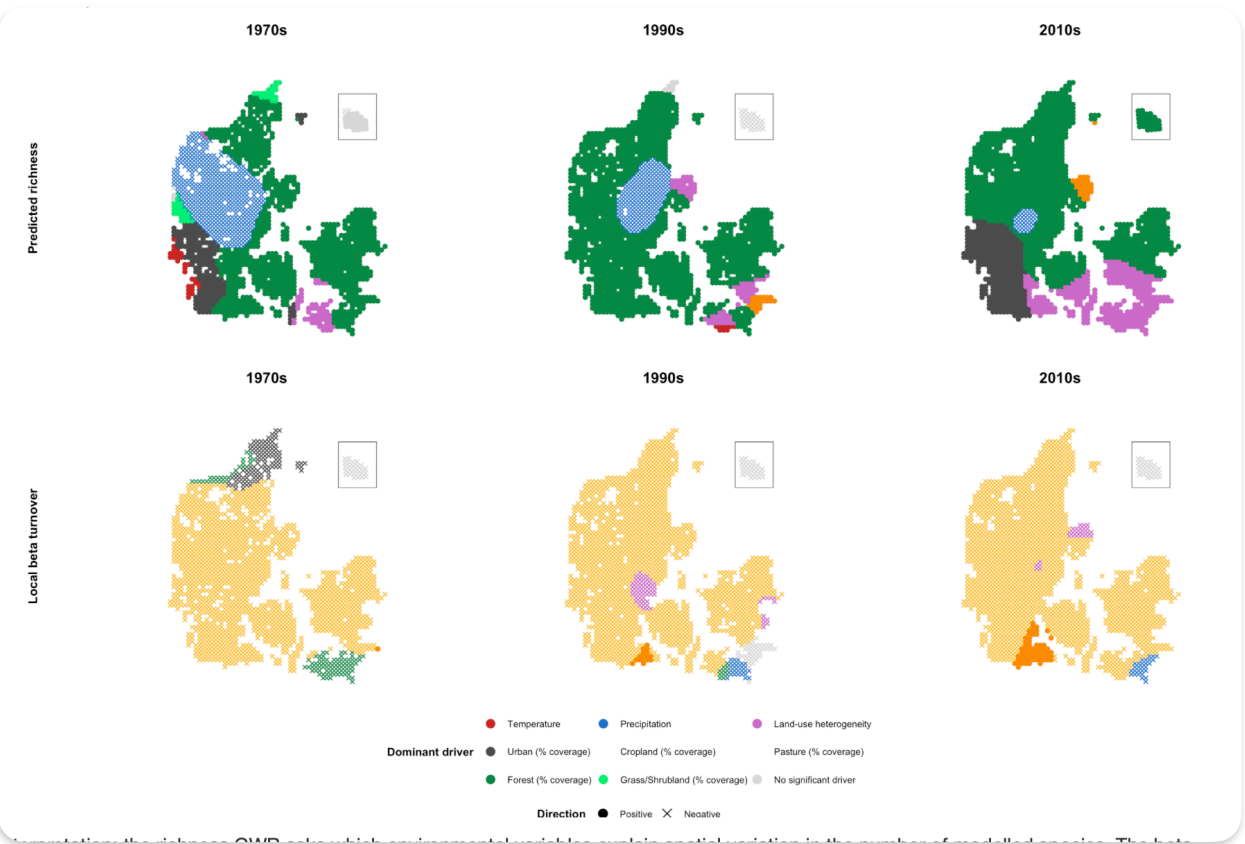

2. Forests + croplands most important through time

How do these variables affect avifaunal community patterns across the landscape? Are they a positive for richness and diversity?

1. Forests foster richness, croplands inhibit turnover

2. Some spatiotemporal variation in local drivers or richness / diversity, both in climate and land-use variables

Can these shifting impacts be explained through the lens of species ecological characteristics?

1. Later importance of (1) urban, (2) pastures and (3) forests may explained by warm (1) affinity species & sedentary species, (2) scolopacids & dabbling ducks and (3) small insectivorous passerines

2. Increasing role of heterogeneity likely not reflected, as almost everyone benefits from increasing heterogeneity?

3. Role of precipitation & grasslands on structuring richness is not clear through these traits, maybe equal influence on all species.
